

Interrealm in Gno

A deep dive into Gno's realm system and rules

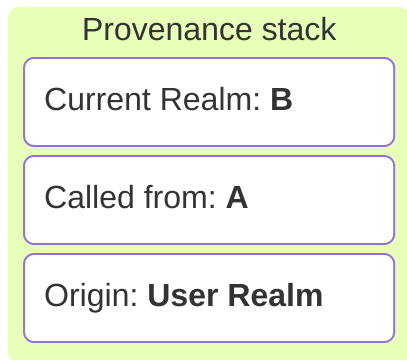

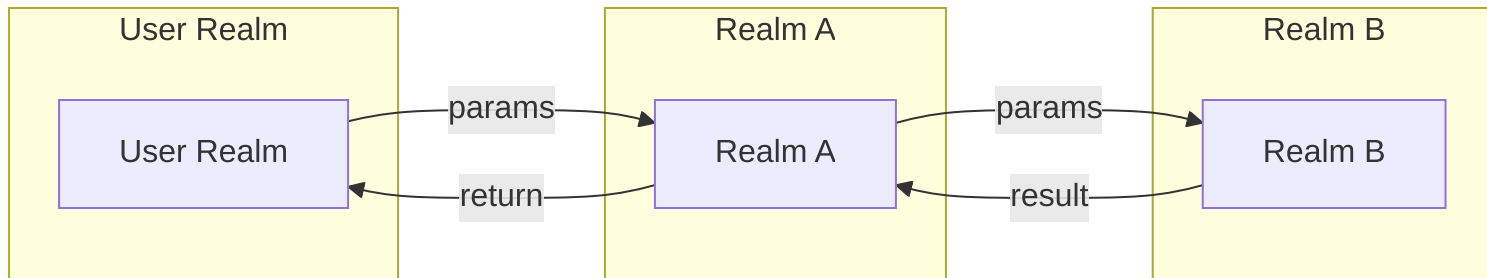

What is a Realm?

- A **realm** is an isolated execution and storage context 🌐
- Each realm has:
 - Its own **state and authority**
 - Rules for **entry** and **data modification**
- Realms enforce:
 - **Security, Traceability** and **Isolation**

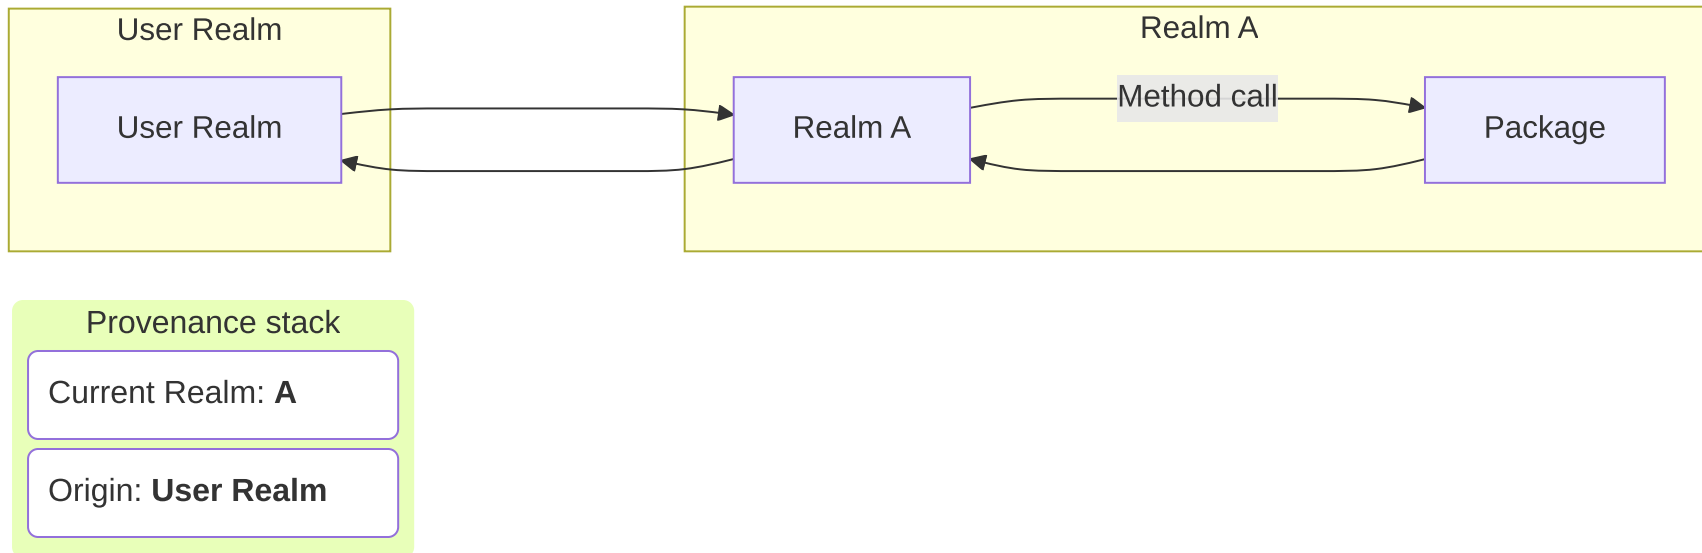

Interrealm Flow

Realm method call

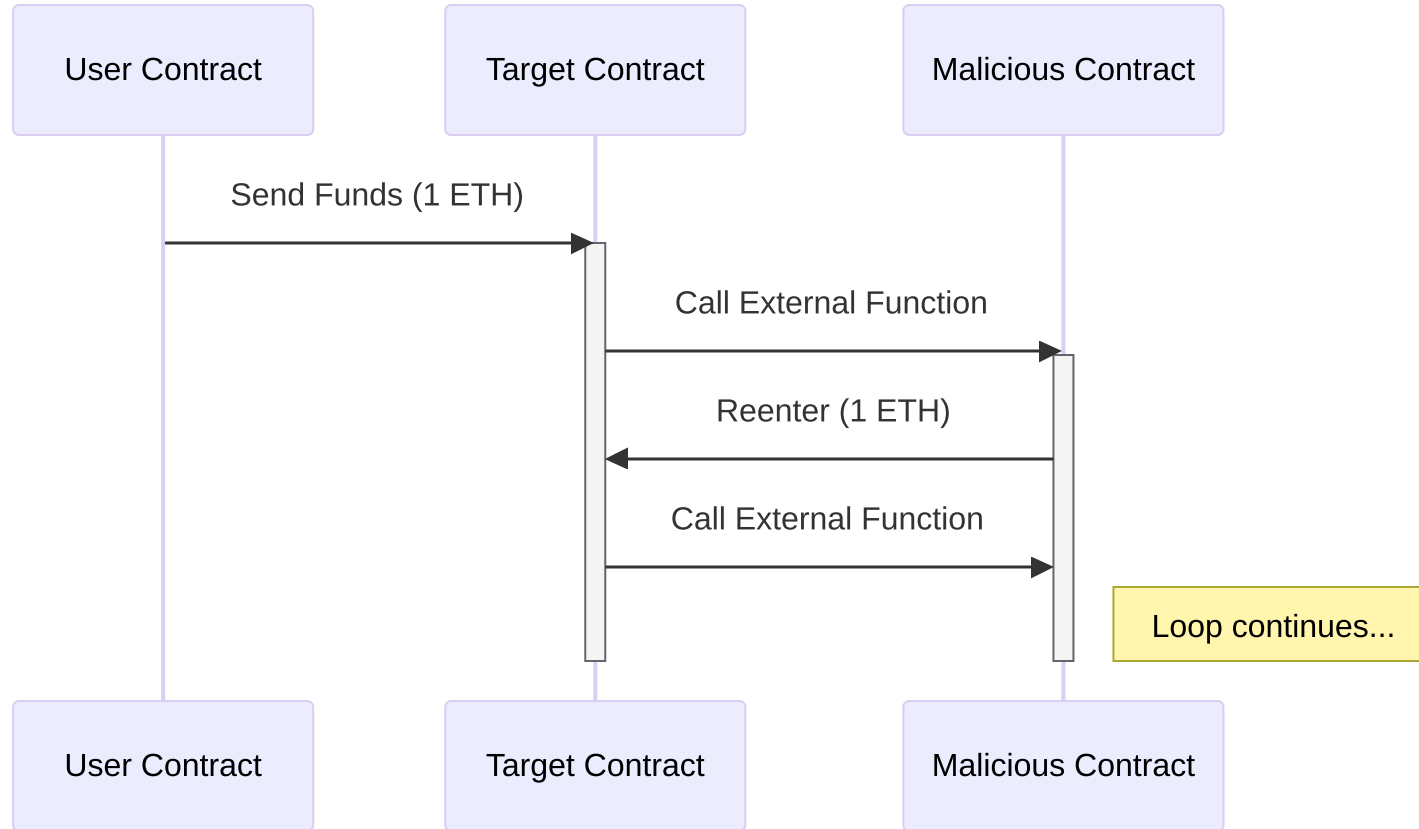

Interrealm Flow

Package method call

But it instaure crucial flaw - Reentrancy attack

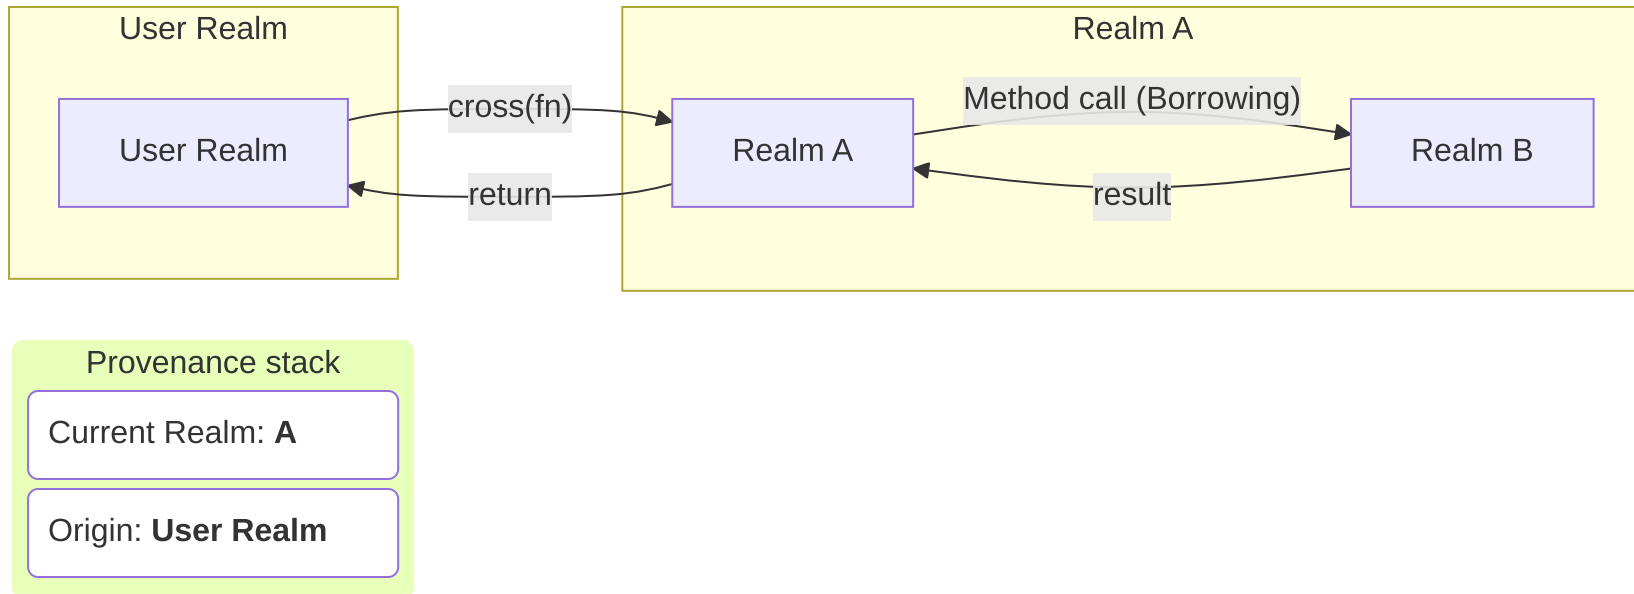

Let's introduce **Borrowing**

Less permissive call for a more secure environment.

- **Borrowing** = calling a method on an object in another realm.
- You **implicitly visit** the object's realm for that method call.
- You can **read and modify** the receiver and its reachable state.
- **Limit:** You cannot freely create new root-level objects.

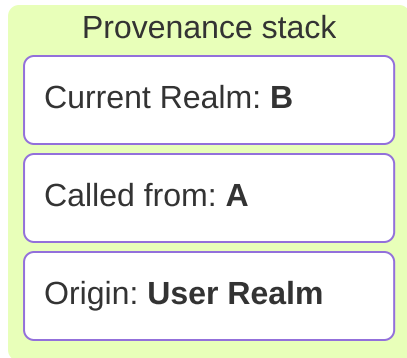

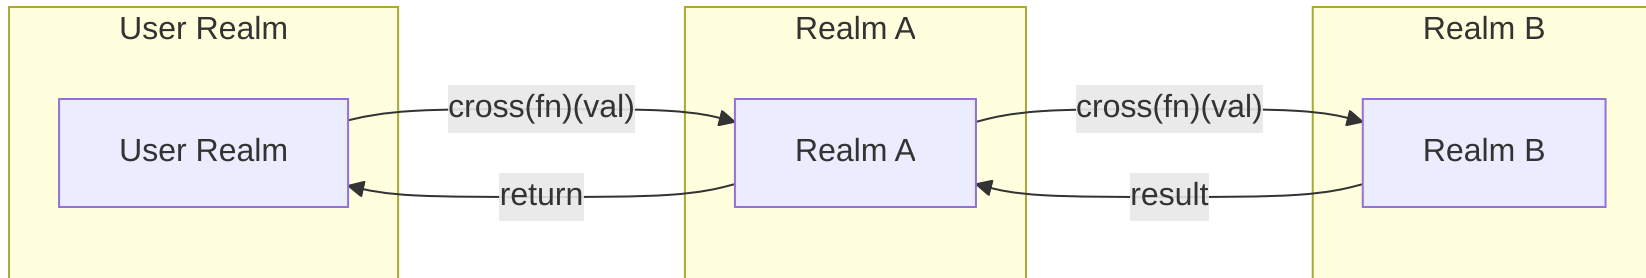

Interrealm Flow (Borrowing)

Crossing

- **Explicitly switch** into another realm.
- **Crossing** = `cross(fn)(...)` or functions marked with `crossing()`.
- Gain full **write access** to the realm's global storage like it used to.
- Use for **creating new objects** or performing realm-specific logic.

Interrealm Flow (Crossing)

Inter-realm Flow (Crossing)

Realm A

```
func CallCreatePost(title, content string) {  
    cross(CreatePost)(title, content)  
}
```

Realm B

```
func CreatePost(title, content string) {  
    newPost := Post{  
        Title: title,  
        Content: content,  
    }  
    Posts = append(Posts, *newPost)  
}
```

Rules Summary

Action	Borrowing	Crossing
Modify existing object	✓ via method call	✓
Create new unattached object	✗	✓
Implicit realm context change	No (temporary for method)	Yes (permanent inside fn)
Method syntax	<code>obj.Method()</code>	<code>cross(fn)(...)</code> + <code>crossing()</code>

Code Example: Borrowing

```
// In realmB
func (b *Book) SetTitle(new string) {
    b.Title = new // Allowed: borrowing b's realm
}

// In realmA
book := &realmB.Book{}
book.SetTitle("Hello Gno")
```

Code Example: Crossing

```
// In realmB
func CreateUser(name string) {
    crossing()
    user := &User{Name: name}
    users[name] = user // Global storage in realmB
}

// In realmA
cross(realmB.CreateUser)("alice")
```

Best Practices

1. Default to **non-crossing** methods.
2. Use **borrowing** for object-specific ops.
3. Reserve **crossing** for realm-level state changes.
4. Always mark public crossable functions with `crossing()` .

Summary

- **Realms** = isolated worlds.
- **Borrowing** = temporary, object-scoped access.
- **Crossing** = explicit realm switch for full access.
- Choose the right approach for **security** and **clarity**.
